### Abstract

Thousands of chemicals have been profiled by high-throughput screening programs such as ToxCast and Tox21; these chemicals are tested in part because most of them have limited or no data on hazard, exposure, or toxicokinetics. Toxicokinetic models aid in predicting tissue concentrations resulting from chemical exposure, and a “reverse dosimetry” approach can be used to predict exposure doses sufficient to cause tissue concentrations that have been identified as bioactive by high-throughput screening. We have created four toxicokinetic models within the R software package **httk**. These models are designed to be parameterized using high-throughput *in vitro* data (plasma protein binding and hepatic clearance), as well as structure-derived physicochemical properties and species-specific physiological data. The package contains tools for Monte Carlo sampling and reverse dosimetry along with functions for the analysis of concentration vs. time simulations. The package can currently use human *in vitro* data to make predictions for 553 chemicals in humans, rats, mice, dogs, and rabbits, including 94 pharmaceuticals and 415 ToxCast chemicals. For 67 of these chemicals, the package includes rat-specific *in vitro* data. This package is structured to be augmented with additional chemical data as they become available. Package **httk** enables the inclusion of toxicokinetics in the statistical analysis of chemicals undergoing high-throughput screening.

*Keywords:* high-throughput, ToxCast, **httk**, toxicokinetics, pharmacokinetics.

---

## 1. Introduction

Humans are exposed to thousands of chemicals from the environment and consumer products, most of which have not been tested for toxicity (Park *et al.* 2012; Wambaugh *et al.* 2013b;

Egeghy *et al.* 2011; Judson *et al.* 2008). In order to screen for potential bioactivity, *in vitro* data have been generated in the Tox21 (Bucher 2008) and ToxCast (Judson *et al.* 2010) programs using high-throughput screening systems. Over 8500 chemicals have been tested in at least 50 assays (Tox21), and a subset of around 1800 have had nearly 1200 assay endpoints measured (ToxCast). Recently, high-throughput exposure modeling has provided estimates of daily human exposure for thousands of environmental contaminants (Wambaugh *et al.* 2014). However, linking these hazard and exposure predictions to estimate risk requires development and use of high-throughput toxicokinetics. The terms “pharmacokinetic”, “toxicokinetic”, and “biokinetic” models have been used somewhat interchangeably in the scientific literature. However, since this package is intended to provide dose context to high-throughput toxicity screening projects, we have selected the term “toxicokinetic” even though we include several compounds with known therapeutic benefits and many others that may not cause adversity for the highest plausible dose.

Toxicokinetics is a field of study for determining the absorption, distribution, metabolism, and excretion of substances in the body (O’Flaherty 1981). The necessary data for toxicokinetics are commonly collected in rats and other animals, but the collection of these data for thousands of chemicals is costly in time, money, and animals (Rovida and Hartung 2009). Creating computational predictive models parameterized with more easily obtained *in vitro* data may help address these problems. Inputting estimated exposures into toxicokinetic models yields information about the steady state and time course concentrations in various parts of the body. These concentrations can then be compared to concentrations that cause biological activity in *in vitro* assays. The models can also be used in a reverse manner, known as reverse toxicokinetics, by predicting the dose needed to produce a specific concentration of interest, such as the *in vitro*  $AC_{50}$  or other levels of biological activity as done in Wetmore *et al.* (2012) and Wetmore (2015). Thus chemicals can be ranked based on the ratio of the predicted exposure dose to the back-calculated bioactive dose (Thomas *et al.* 2013), which, due to the linearity of these models, is equal to the ratio of the predicted steady state concentration to the *in vitro* bioactive concentration.

Many basic toxicokinetic models (Wetmore *et al.* 2012; Wetmore 2015; Pelekis *et al.* 1997) only predict steady state plasma concentrations ( $C_{ss}$ ), assuming a dose rate that is both continuous and constant (e.g., infusion dose). With a more dynamic model, such as a physiologically based toxicokinetic (pbtk) model, we can simulate discrete doses to reach steady state, which we observe to oscillate around the infusion dose prediction. Our pbtk models include multiple compartments with partition coefficients. These models are expressed as a set of mass balance differential equations describing the rate of change of the amount of a substance in each compartment. Chemical-specific physicochemical data and species-specific *in vitro* and physiological data are used in calculating the partition coefficients, clearance, tissue volumes, and blood flows. These *in vitro* data consist of the intrinsic hepatic clearance,  $Cl_{int}$ , and the plasma protein binding,  $f_{ub}$ . **httk** provides tools for Monte Carlo sampling and reverse dosimetry (Tan *et al.* 2006) along with functions that solve for concentration vs. time curves, steady state concentrations, the number of days to steady state, and other toxicokinetic summary statistics for chemicals as shown in Tables 4 and 5 with the corresponding abbreviations in Table 1. With this R package we provide data, models, and examples to allow the inclusion of toxicokinetics in statistical analysis of chemical exposure and toxicity for 553 chemicals. The package is structured to be modular and expandable to allow new modeling approaches and chemical data to be added as they become available.

Variable	Name
1compartment	One compartment model (O’Flaherty 1981), shown in Figure 1.
3compartment	Three compartment model (Jamei <i>et al.</i> 2009), shown in Figure 1.
3compartments	Three compartment steady state model (Wetmore <i>et al.</i> 2012; Wetmore 2015).
BW	Body weight.
$C_{ss}$	Average plasma concentration of a chemical at steady state.
$Cl_{int}$	<i>In vitro</i> intrinsic hepatic clearance.
$Cl_{metabolism}$	Whole liver hepatic clearance, scaled from $Cl_{int}$ .
$Cl_{well-stirred}$	Hepatic clearance modeled with well-stirred approximation using $Cl_{metabolism}$ .
$f_{ub}$	Fraction unbound, <i>in vitro</i> ratio of unbound to total concentration in plasma.
httk	High-throughput toxicokinetics.
$k_{elim}$	Elimination rate.
$k_{gutabs}$	Gut absorption rate, default of $1 h^{-1}$ .
logP	Logarithm (base 10) of octanol to water partition coefficient.
pbtk	Physiologically based toxicokinetic model, shown in Figure 1.
PM	Poor metabolizers.
$Q_{cardiac}$	Cardiac output, blood flow through the heart and lungs.
$Q_{gfr}$	Glomerular filtration rate.
$Q_{rest}$	The difference between $Q_{cardiac}$ and the flow to the liver, kidney, and gut.
$Q_{tissue}$	Blood flow to a tissue.
QSAR	Quantitative structure-activity relationship.
$R_{blood2plasma}$	Ratio of the blood concentration of a chemical to the plasma concentration.
SBML	Systems biology markup language.
SMILES	Simplified molecular-input line-entry system.
$V_{dist}$	Volume of distribution, the weighted sum of all partition coefficients.

Table 1: List of abbreviations.

## 2. Methods

Version 1.7 of **httk** (Wambaugh *et al.* 2017) is used in this manuscript. The package is available from the Comprehensive R Archive Network (CRAN) at <https://CRAN.R-project.org/package=httk>.

### 2.1. Models included

The four models in **httk** include: “pbtk”, “3compartment”, “3compartments”, and “1compartment”; the predictions and parameters of these models are compared in Table 2. All models currently use only oral and intravenous (i.v.) dosing. The models pbtk and 3compartment, shown in Figure 1, use tissue to unbound plasma partition coefficients calculated with a modified version of Schmitt’s model (Schmitt 2008b) (using octanol-water partitioning, membrane affinity, acid/base dissociation constants, tissue compositions, and adjusted  $f_{ub}$ ) to simulate chemical concentrations over time for multiple tissue compartments. The

Model	Hepatic clearance	Partition coefficients	Fraction unbound	Hematocrit	Molecular weight	Ratio of blood to plasma	Elimination rate*	Volume of distribution*	Dynamic prediction	Steady state prediction
pbtck	Yes	Yes	Yes	Yes	Yes	Yes	No	No	Yes	Yes
1compartment	No	No	No	No	Yes	No	Yes	Yes	Yes	Yes
3compartment	Yes	Yes	Yes	Yes	Yes	Yes	No	No	Yes	Yes
3compartmentss	Yes	No	Yes	No	Yes	No	No	No	No	Yes

Table 2: Model parameter and prediction comparison. \*Partition coefficients are needed in calculating  $V_{dist}$ . Clearances and  $f_{ub}$  are needed in calculating  $k_{elim}$ .

model pbtck contains separate tissue compartments for the gut, liver, lungs, arteries, veins, and kidneys while the model 3compartment only contains compartments for the liver and gut and is essentially a condensed form of the model pbtck. The tissues contained in `tissue.data` that are unused in each of these models are aggregated into a single compartment termed “rest”, whose partition coefficient is calculated by averaging the remaining partition coefficients, weighted by their species-specific tissue volumes. Absorption from the gut lumen into gut tissue is modeled as a first order process with an arbitrary “fast” absorption rate of  $1 h^{-1}$ . The fraction of the dose absorbed into the system through the gut wall is set to 1 when measured data are unavailable. The gut blood flows directly into the liver, where the hepatic clearance,  $Cl_{metabolism}$ , is calculated with a unit conversion of  $Cl_{int}$  using the density of hepatocytes in the liver ( $1.1 \times 10^8$  hepatocytes per gram of liver from Ito and Houston 2004 and a liver density of 1.05 g/mL from Snyder *et al.* 1975). Both models also feature renal elimination by passive glomerular filtration through the kidneys. We assume perfusion-limited tissue (i.e., tissue, red blood cells, and plasma come to equilibrium rapidly with respect to the flow of blood), and a constant  $R_{blood2plasma}$  is used throughout the body, predicted using hematocrit and the predicted partitioning between red blood cells and plasma when *in vivo* values are unavailable.

The models 3compartmentss and 1compartment both contain only plasma without separate compartments for blood and tissue (and thus no individual partition coefficients). The model 3compartmentss, “ss” standing for steady state, is a single equation for the  $C_{ss}$  of the rest-of-body compartment in the model 3compartment resulting from i.v. dosing. This is the same equation used for determining  $C_{ss}$  in previous work (Rotroff *et al.* 2010; Wetmore *et al.* 2012; Wetmore 2015; Wilkinson and Shand 1975) but with a modification adjusting for the misuse of hepatic blood flow in determining plasma clearance (Yang *et al.* 2007). The model 1compartment features an absorption compartment and a total clearance equal to the sum of the metabolism of the parent compound in the liver, modeled with the adjusted “well-stirred” approximation (Wilkinson and Shand 1975; Houston and Carlile 1997), and the renal clearance by passive glomerular filtration. The elimination rate,  $k_e$ , is equal to the total clearance divided by the volume of distribution,  $V_{dist}$ .  $V_{dist}$  is used as the volume of the compartment and is calculated by summing the plasma volume and the products of each tissue to unbound plasma partition coefficient, its corresponding volume, and  $f_{ub}$  (Schmitt

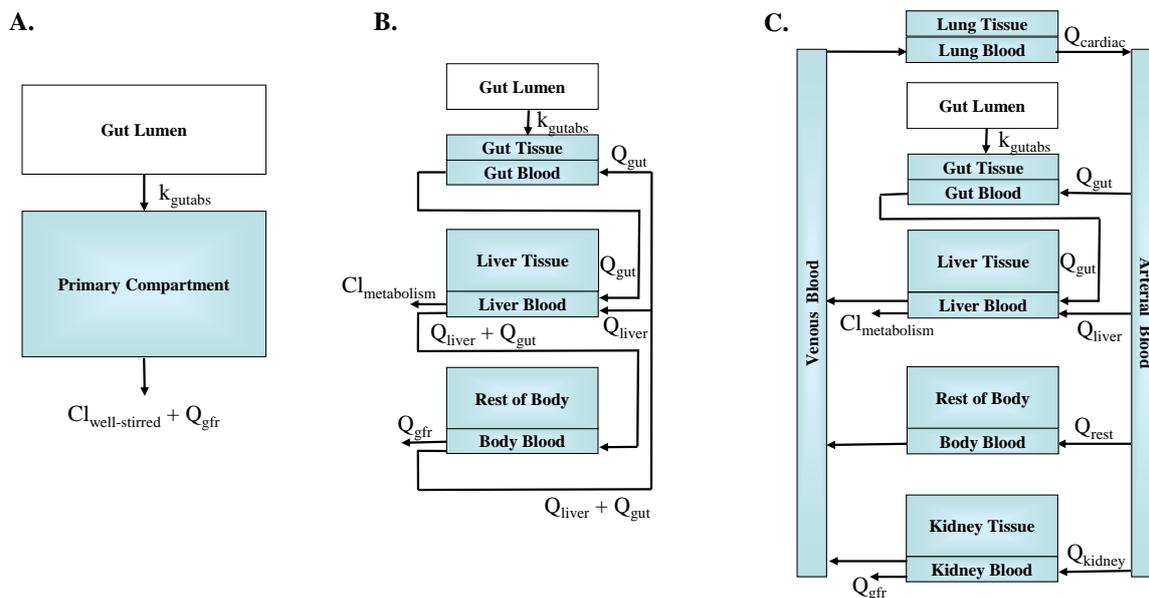

Figure 1: Models (A) 1compartment, (B) 3compartment, and (C) pbtk. In order to preserve mass-balance,  $Q_{rest}$  is defined as the difference between  $Q_{cardiac}$  and the flow to the liver, kidney, and gut. Variable names are defined in Table 1.

2008b).  $C_{ss}$  resulting from infusion dosing for the model 1compartment is equivalent to 3compartmentss.

Among the four models in the package, the simplest model, 3compartmentss, is applicable to the largest number of chemicals, specifically those which are missing information needed to parameterize the other models. It is the only model that does not use partition coefficients and thus does not require  $\log P$ , and when  $f_{ub}$  is below the limit of detection, the model can be used with Monte Carlo to simulate  $C_{ss}$  distributions. Thus,  $f_{ub}$  below the limit of detection (set to zero in `chem.physical_and_invitro.data` and 0.005 in default parameter lists) and  $Cl_{int}$  are the minimum data requirements for running a model. The model 1compartment is included to compare our predictions with *in vivo* experiments which are often characterized by one compartment model parameters ( $V_{dist}$  and  $k_{elim}$ ). We note that fully understanding the kinetics of a given chemical might require additional data on features currently not accessible with high-throughput *in vitro* approaches, such as bioavailability, transporters, protein-binding kinetics, and extra-hepatic or strongly saturable metabolism (Rotroff *et al.* 2010).

## 2.2. Model equations

The differential equations below describe changes in the concentrations or amounts of a substance within the model compartments. Although the models are written as changes in tissue concentrations, except for the gut lumen, the equations actually express changes in the amount of substance in the blood of each tissue divided by the tissue volume with the blood and tissue concentrations related through the out-flowing concentration in blood. A

blood flow,  $Q$  (L/day), multiplied by a concentration,  $C$  (mol/L), is equal to the amount of the substance entering or leaving a compartment through the blood,  $QC$  (mol/day). We define partition coefficients as the ratio of the concentration in a tissue to the unbound concentration in plasma of that tissue;  $K_{tissue2pu} = C_{tissue}/(f_{ub}C_{plasma})$ . Thus dividing  $C_{tissue}$  by  $K_{tissue2pu}$  and  $f_{ub}$  and then multiplying by  $R_{blood2plasma}$  yields the blood concentration of the compartment at equilibrium,  $C_{tissue}R_{blood2plasma}/(f_{ub}K_{tissue2pu})$ . Assuming perfusion-limited tissue, we substitute this term for the out-flowing blood concentrations (Campbell Jr *et al.* 2012) and assume negligible blood volume fractions in all tissues to justify dividing by the tissue volume without a blood volume fraction and partition coefficient dependency. The flow to the rest-of-body,  $Q_{rest}$ , is calculated by subtracting the sum of all the other tissue flows (i.e., gut, liver, and kidney) from the total cardiac output. The glomerular filtration rate,  $Q_{gfr}$ , and the hepatic clearance,  $Cl_{metabolism}$ , (both in L/day) are both multiplied by the unbound plasma concentrations,  $C_{tissue}/K_{tissue2pu}$ , in the kidney and liver to express the amount of the substance leaving the system. Note that although the units of the clearances, flows, and absorption rate are in days, being consistent with the model outputs, they are initially entered in units of hours. The model 3compartmentss assumes a constant dose rate,  $k_{dose}$  (mg/kg BW/day), and the other models use discrete changes in the amount in the gut lumen or venous concentration, depending on which type of dose is specified. The function that is part of the gut lumen equation,  $g(t)$  describes the oral dosing schedule. **MCSim** (Bois and Maszle 1997) was used for converting the model equations into C code, which is used with **deSolve** (Soetaert *et al.* 2016) in solving each system of equations.

*pbt*k equations

$$\begin{aligned}
\frac{d}{dt}A_{gutlumen} &= -k_{gutabs}A_{gutlumen} + g(t) \\
\frac{d}{dt}C_{gut} &= \left( k_{gutabs}A_{gutlumen} + Q_{gut} \left( C_{art} - \frac{R_{blood2plasma}}{K_{gut2pu}f_{ub}} C_{gut} \right) \right) / V_{gut} \\
\frac{d}{dt}C_{liver} &= \left( Q_{liver}C_{art} + \frac{Q_{gut}R_{blood2plasma}}{K_{gut2pu}f_{ub}} C_{gut} - \right. \\
&\quad \left. \frac{(Q_{liver} + Q_{gut})R_{blood2plasma}}{K_{liver2pu}f_{ub}} C_{liver} - \frac{Cl_{metabolism}}{K_{liver2pu}} C_{liver} \right) / V_{liver} \\
\frac{d}{dt}C_{ven} &= \left( \left( \frac{Q_{liver} + Q_{gut}}{K_{liver2pu}} C_{liver} + \frac{Q_{kidney}}{K_{kidney2pu}} C_{kidney} + \right. \right. \\
&\quad \left. \left. \frac{Q_{rest}}{K_{rest2pu}} C_{rest} \right) \frac{R_{blood2plasma}}{f_{ub}} - Q_{cardiac} C_{ven} \right) / V_{ven} \\
\frac{d}{dt}C_{lung} &= Q_{cardiac} \left( C_{ven} - \frac{R_{blood2plasma}}{K_{lung2pu}f_{ub}} C_{lung} \right) / V_{lung} \\
\frac{d}{dt}C_{art} &= Q_{cardiac} \left( \frac{R_{blood2plasma}}{K_{lung2pu}f_{ub}} C_{lung} - C_{art} \right) / V_{art} \\
\frac{d}{dt}C_{rest} &= Q_{rest} \left( C_{art} - \frac{R_{blood2plasma}}{K_{rest2pu}f_{ub}} C_{rest} \right) / V_{rest} \\
\frac{d}{dt}C_{kidney} &= \left( Q_{kidney}C_{art} - \frac{Q_{Kidney}R_{blood2plasma}}{K_{kidney2pu}f_{ub}} C_{kidney} - \frac{Q_{gfr}}{K_{kidney2pu}} C_{kidney} \right) / V_{kidney}
\end{aligned}$$

### 3compartment equations

$$\begin{aligned} \frac{d}{dt}A_{gutlumen} &= -k_{gutabs}A_{gutlumen} + g(t) \\ \frac{d}{dt}C_{gut} &= \left( k_{gutabs}A_{gutlumen} + \frac{Q_{gut}R_{blood2plasma}}{K_{rest2pu}f_{ub}}C_{rest} - \frac{Q_{gut}R_{blood2plasma}}{K_{gut2pu}f_{ub}}C_{gut} \right) / V_{gut} \\ \frac{d}{dt}C_{liver} &= \left( \frac{Q_{gut}R_{blood2plasma}}{K_{gut2pu}f_{ub}}C_{gut} + \frac{Q_{liver}R_{blood2plasma}}{K_{rest2pu}f_{ub}}C_{rest} - \right. \\ &\quad \left. \left( \frac{(Q_{liver} + Q_{gut})R_{blood2plasma}}{f_{ub}K_{liver2pu}} + \frac{Cl_{metabolism}}{K_{liver2pu}} \right) C_{liver} \right) / V_{liver} \\ \frac{d}{dt}C_{rest} &= \left( \frac{(Q_{gut} + Q_{liver})R_{blood2plasma}}{f_{ub}K_{liver2pu}}C_{liver} - \right. \\ &\quad \left. \left( \frac{R_{blood2plasma}}{f_{ub}}(Q_{gut} + Q_{liver}) + Q_{gfr} \right) \frac{C_{rest}}{K_{rest2pu}} \right) / V_{rest} \end{aligned}$$

### 1compartment equations

$$\begin{aligned} \frac{d}{dt}A_{gutlumen} &= -k_{gutabs}A_{gutlumen} + g(t) \\ \frac{d}{dt}C_{rest} &= \frac{k_{gutabs}}{V_{dist}}A_{gutlumen} - k_{elim}C_{rest} \end{aligned}$$

### 3compartmentss equation

$$C_{ss} = k_{dose} / \left( f_{ub}Q_{gfr} + \frac{(Q_{liver} + Q_{gut})f_{ub}Cl_{metabolism}}{(Q_{liver} + Q_{gut}) + f_{ub}Cl_{metabolism}/R_{blood2plasma}} \right)$$

## 2.3. In vitro chemical data

*In vitro* experiments provide empirical data for two model parameters. The first,  $Cl_{int}$ , the intrinsic hepatic clearance of the parent compound by primary hepatocytes (substrate depletion approach), was measured in a well on a multi-compound plate (Shibata *et al.* 2002). This was determined by dividing the *in vitro* clearance of the unbound parent chemical by the fraction of chemical unbound in the hepatocyte intrinsic clearance assay provided in the parameter lists, which was estimated using a distribution coefficient calculated from pKa and the method of Kilford *et al.* (2008). The second *in vitro* measurement is  $f_{ub}$ , assessed using rapid equilibrium dialysis (RED) in which two wells are separated by a membrane that is permeable by smaller molecules but prevents the plasma protein added to one well from migrating to the other well (the relative chemical concentration in the two linked wells gives the free fraction of chemical; Waters *et al.* 2008). However, the default value used in the models is adjusted for absent binding *in vitro* (Poulin and Haddad 2012).

Data table	Description
<code>chem.invivo.PK.data</code>	This data set includes time and dose specific measurements of chemical concentrations in tissues taken from animals administered control doses of the chemicals either orally or intravenously. These plasma concentration-time data are from rat experiments reported in public sources. Toxicokinetic data were retrieved from those studies by the Netherlands Organisation for Applied Scientific Research (TNO) using curve stripping (TechDig v2). These data are provided for statistical analysis as in <a href="#">Wambaugh <i>et al.</i> (2015)</a> .
<code>chem.invivo.PK.-summary.data</code>	This data set summarizes the time course data in the <code>chem.invivo.PK.data</code> table. Maximum concentration (Cmax), time integrated plasma concentration for the duration of treatment (AUC.treatment) and extrapolated to zero concentration (AUC.infinity) as well as half-life are calculated. Summary values are given for each study and dosage.
<code>chem.physical_and_invitro.data</code>	This data set contains the necessary information to make basic, high-throughput toxicokinetic predictions for compounds, including $f_{ub}$ , $Cl_{int}$ , molecular weight, logP, logMA (membrane affinity), and pKa.
<code>tissue.data</code>	This data set contains values from <a href="#">Ruark <i>et al.</i> (2014)</a> describing the composition of specific tissues and from <a href="#">Snyder <i>et al.</i> (1975)</a> and <a href="#">Birnbaum <i>et al.</i> (1994)</a> describing volumes of and blood flows to those tissues, allowing parameterization of toxicokinetic models for human, mouse, rat, dog, or rabbit.
<code>physiology.data</code>	This data set contains additional physiological values necessary to parameterize a toxicokinetic model for human, mouse, rat, dog, or rabbit.
<code>Wetmore.data</code>	This data set gives the chemical-specific predictions for serum concentration at steady state resulting from infusion exposure at a constant rate, as published in a series of papers from Barbara Wetmore's group ( <a href="#">Wetmore <i>et al.</i> 2012, 2013</a> ; <a href="#">Wetmore 2015</a> ) at the Hamner Institutes for Life Sciences. Predictions include the median and 90% interval in $\mu\text{M}$ and mg/L. Calculations were made using the 1 and 10 $\mu\text{M}$ <i>in vitro</i> measured clearances.

Table 3: List of data tables in the package. In [Ring \*et al.\* \(2017\)](#), a series of tables for generating populations based on variation in human physiology were added. They are described in that manuscript and vignettes.

For non-pharmaceutical chemicals, *in vitro* experimental data were obtained primarily from [Wetmore \*et al.\* \(2012\)](#), [Wetmore \(2015\)](#), and [Tonnelier \*et al.\* \(2012\)](#) for humans and [Wetmore \*et al.\* \(2013\)](#) for rats. For pharmaceutical compounds these values are compiled from [Obach \(1999\)](#), [Jones \*et al.\* \(2002\)](#), [Naritomi \*et al.\* \(2003\)](#), [Ito and Houston \(2004\)](#), [Riley \*et al.\* \(2005\)](#), [Schmitt \(2008a\)](#), and [Obach \*et al.\* \(2008\)](#). These data are contained in `chem.physical_and_invitro.data`.

## 2.4. Physicochemical properties

Physicochemical properties were collated from various sources: Molecular weight and structure are determined from the DSStox database (<http://www.epa.gov/ncct/dsstox>), and octanol to water partitioning is predicted for most compounds with EPA's estimation program interface (EPI) suite (<http://www.epa.gov/tsca-screening-tools/epi-suite-estimation-program-interface>). EPI suite quantitative structure activity relationships (QSARs) were used to estimate octanol to water partitioning (logP) if simplified molecular input line entry system (SMILES) descriptions of chemical structure were available and the QSARs did not fail for that structure. In addition to QSAR model estimates, EPI suite contains a database of experimentally obtained octanol to water partition coefficients that were used in place of estimated values when available. Where available, ionization association/dissociation equilibrium constants (pKa) were curated from the literature; otherwise predictions were made from structure using the SPARC (which performs automated reasoning in chemistry) model (Hilal *et al.* 1995). Membrane affinities (i.e., lipid-bilayer to water concentration ratios) are predicted using a regression from Yun *et al.* (2014), based on octanol to water partitioning and membrane affinity values from Schmitt (2008b), when measured values are unavailable. These data are contained in `chem.physical_and_invitro.data`.

## 2.5. Physiological and tissue data

The tissue data needed for calculating partition coefficients in human and rat, taken from Ruark *et al.* (2014), include: cellular and water fractions of total volume, lipid and protein fractions of cellular volume, lipid fractions of the total lipid volume, the pH of each tissue, and the fractional volume of protein in plasma. A default plasma pH of 7.4 is taken from Schmitt (2008b) in calculating ionization. The partition coefficient for the mass and volume of the body unaccounted for by the tissues included in Schmitt (2008b) is calculated with the averages of the fractional volumes and pH of these tissues, excluding red blood cells. Tissue volumes and liver density are taken from Snyder *et al.* (1975). Blood flows are from Birnbaum *et al.* (1994). Tissue volumes are scaled linearly to body weight while the flows, including glomerular filtration, are scaled by body weight to the 3/4 power (Campbell Jr *et al.* 2012). The available data for the fraction of a dose absorbed into the gut lumen are taken from Naritomi *et al.* (2003). The remaining data are taken from Davies and Morris (1993). These data are included in the `physiology.data` and `tissue.data` tables that are accessible in the package.

## 2.6. Determination of steady state

Although the discrete dosing in our models produces an oscillating steady state, we use the steady state resulting from equivalent oral infusion dosing at a constant rate, calculated by analytically solving the differential equations at steady state, to determine when steady state is reached. The day a chemical reaches steady state is found by determining when the average concentration of the numerically solved solution for a given day falls within a specified percent of the analytic solution from oral infusion dosing, `calc_css` defaulting to 1%.

## 2.7. Monte Carlo sampler

The package contains a Monte Carlo sampler, HHTK-Pop (Ring *et al.* 2017), used in

`calc_mc_css` for probabilistically simulating human biological variability and measurement uncertainty in parameters determining  $C_{ss}$  (Thomas *et al.* 1996). HTTK-Pop uses physiologies based on distributions of demographic and anthropometric quantities from the most recent U.S. Centers for Disease Control and Prevention National Health and Nutrition Examination Survey (NHANES) data (Johnson *et al.* 2014). This allows incorporation of inter-individual variability, including variability across relevant demographic subgroups which can be specified through the arguments `gendernum`, `agelim_years/agelim_months`, `weight_category`, `gfr_category`, and `reths`, respectively specifying the relative numbers of genders, age ranges, body weights, kidney function, and racial ethnicity for the simulated population. By default, the total U.S. population is represented (Johnson *et al.* 2014). HTTK-Pop accounts for the correlation structure in physiological parameters (Ring *et al.* 2017). Two methods for sampling individuals are available: the default, direct resampling (`method="dr"`) uses actual individuals from the NHANES. If the number of individuals for a specific demographic group is small, larger numbers of virtual individuals (`method="vi"`) can be generated. Prior to version 1.5, the package relied upon a Monte Carlo sampler that used uncorrelated normal distributions that were truncated to ensure positive values. The distributions can be changed, but default to a mean equal to the model parameter estimate and a coefficient of variation of 0.3. For humans, setting `httkpop` to `FALSE` allows the original uncorrelated Monte Carlo sampler to be used. HTTK-Pop is only used for humans, and so for all non-human species the original sampler is still used.

Body weight, liver volume and blood flow, cellular density in the liver, and  $Q_{gfr}$  are all varied as described above. HTTK-Pop varies  $Cl_{metabolism}$  by varying three quantities. Hepatocellularity ( $10^6$  cells/g liver) and liver weight (kg) are varied based on NHANES biometrics (Ring *et al.* 2017). The chemical specific *in vitro* measured  $Cl_{int}$  is varied according to a Gaussian mixture distribution to represent the population proportions of poor metabolizers (PMs) and non-PMs of each substance. With probability 0.95,  $Cl_{int}$  was drawn from a non-PM distribution: a normal distribution truncated below at zero, centered at the value measured *in vitro*, with a coefficient of variation of 0.3. With probability 0.05,  $Cl_{int}$  was drawn from a PM distribution: a truncated normal distribution centered on one-tenth of the *in vitro* value with coefficient of variation 0.3.  $f_{ub}$  is drawn from a censored distribution with identical properties to the other distributions, where values are sampled from a uniform distribution between 0% and the limit of detection (default of 1% unbound) at a rate proportional to the number of samples from the truncated normal distribution below the limit of detection.  $f_{ub}$  below the limit of detection (set to zero in `chem.physical_and_invitro.data`) is set to a default value of 0.005 in the model parameters. For each chemical, a default of 1000 different combinations of parameters are used to determine  $C_{ss}$ . These concentrations are determined with doses of 1 mg/kg BW/day but, given the linear concentration response of the models, can be extrapolated to other doses with `calc_mc_css`. Using `calc_mc_oral_equiv`, we can, in a reverse manner, back-calculate the dose for a given concentration and quantile. The functions `get_wetmore_css` and `get_wetmore_oral_equiv` perform the same operations on doses and concentrations using the published  $C_{ss}$  results from Wetmore *et al.* (2012), Wetmore *et al.* (2013), and Wetmore (2015), contained in the `Wetmore.data` table, which used the same *in vitro* data as contained in the package. However, these data only contain the 5%, median, and 95% quantiles for humans and the median for rats. These results were obtained with the **SimCYP** population simulator (Jamei *et al.* 2009) in a manner identical to the default simulation in `calc_mc_css` with two exceptions. The Wetmore data assumed  $f_{ub} = 0.005$  for

chemicals with  $f_{ub}$  below the limit of detection instead of sampling the value from a censored distribution, and the  $Cl_{metabolism}$  values were accepted as nonzero if the  $p$  value was less than 0.1 instead of 0.05 as used in our sampler.

### 3. Examples

The following examples are run with version 1.7 and may not generate the same outputs as other versions. New versions of the package typically correspond to submission to or revision of manuscripts for peer-reviewed scientific journals (Wambaugh *et al.* 2015; Wetmore 2015; Ring *et al.* 2017). If using **httk** for regulatory purposes, a copy of the version used should be archived. To check if the version installed is 1.7 or greater:

```
R> packageVersion("httk") >= "1.7"
```

#### 3.1. Accessing and changing model parameters

**httk** allows the user to access and change the parameters used in each of the models. Each of the models contains their own `parameterize` function that generates a list of the parameters required by the model. For example, to get a list of parameters for the `pbtk` model of triclosan in a rat:

```
R> parameters <- parameterize_pbtk(chem.name = "triclosan", species = "rat")
```

To see the effect a change in parameters has on the model, we can modify the desired entries in the list and use the new parameter list as an input for the `parameters` argument of a function that uses that model. For example, to change the  $f_{ub}$  in the previous `parameters` list to 0.1 from the default of 0.005 (noting the warning that  $f_{ub}$  is below the limit of detection) and use it in a simulation of the `pbtk` model for a single dose of 1 mg/kg BW of triclosan in a rat:

```
R> parameters["Funbound.plasma"] <- 0.1
R> out <- solve_pbtk(parameters = parameters)
```

Individual parameters such as  $R_{blood2plasma}$ , total clearance,  $V_{dist}$ , metabolic clearance, and  $k_{elim}$  can also be calculated using the functions with the prefix `calc` followed by the parameter name and the same arguments as the above `parameterize` function.

#### 3.2. Making data frames and tables

In order to compare predictions or models, we can construct tables or data frames. Suppose we want to look at how  $C_{ss}$  at 1 mg/kg BW/day compares for the model `pbtk`, the median of the Monte Carlo simulation, and the Wetmore data. We can construct a data frame (used with **ggplot2**, Wickham 2009, in the following examples) containing these data with a for loop. The intersection of `get_wetmore_cheminfo` and `get_cheminfo` contains all the CAS numbers that will work for all three functions. In the example below, setting `model` to `"pbtk"` in `get_cheminfo` removes the chemicals from the list with  $f_{ub}$  below the limit of detection. This is the same as setting `exclude.fub.zero` to `TRUE`. However, we could include these chemicals by using the default model option of `"3compartmentss"`, and  $f_{ub}$  would then automatically be set to 0.005.

Function	Description
<code>add_chemtable</code>	Adds chemical data for HTTK analysis.
<code>available_rblood2plasma</code>	Retrieves $R_{blood2plasma}$ (measured preferred over predicted).
<code>calc_analytic_css</code>	Calculates $C_{ss}$ and blood concentrations for the four models used in the package from infusion dosing at a constant rate.
<code>calc_css</code>	Calculates the maximum and average steady state concentrations along with the day steady state is reached.
<code>calc_elimination_rate</code>	Calculates $k_{elim}$ for a one compartment model due to the liver and kidneys, dividing the total clearance by $V_{dist}$ .
<code>calc_hepatic_clearance</code>	Calculates the hepatic clearance for a well-stirred model or other type if specified (Ito and Houston 2004).
<code>calc_mc_css</code>	Calculates $C_{ss}$ using Monte Carlo simulation, defaulting to HTTK-Pop simulator (Ring <i>et al.</i> 2017).
<code>calc_mc_oral_equiv</code>	Calculates an oral equivalent dose using $C_{ss}$ from <code>calc_mc_css</code> .
<code>calc_rblood2plasma</code>	Calculates the blood:plasma chemical concentration ratio.
<code>calc_stats</code>	Calculates the area under the curve, mean, and peak values for the blood or plasma concentration of either a specified chemical or all chemicals for a given simulation.
<code>calc_total_clearance</code>	Calculates the total clearance rate for a one compartment model where clearance is equal to the sum of the well-stirred metabolism by the liver and glomerular filtration in the kidneys.
<code>calc_vdist</code>	Calculates the one compartment volume of distribution.
<code>export_pbtck_jarnac</code>	Exports the model pbtck to Jarnac (Sauro and Fell 2000).
<code>export_pbtck_sbml</code>	Exports the model pbtck to SBML (Hucka <i>et al.</i> 2003).
<code>get_cheminfo</code>	Provides a list of CAS numbers along with compound names, logP, pKa, molecular weight, $Cl_{int}$ and its $p$ value, and $f_{ub}$ if specified for chemicals with sufficient data for a given model.
<code>get_httk_params</code>	Converts table generated by <code>httkpop_generate</code> to the corresponding table of httk model parameters.
<code>get_rblood2plasma</code>	Retrieves <i>in vivo</i> $R_{blood2plasma}$ .
<code>get_wetmore_cheminfo</code>	Provides the names and CAS numbers of chemicals with information from Wetmore <i>et al.</i> (2012), Wetmore <i>et al.</i> (2013), and Wetmore (2015).
<code>get_wetmore_css</code>	Retrieves $C_{ss}$ as a result of oral infusion dosing from Wetmore <i>et al.</i> (2012), Wetmore <i>et al.</i> (2013), and Wetmore (2015).
<code>get_wetmore_oral_equiv</code>	Calculates an oral equivalent dose using $C_{ss}$ from Wetmore <i>et al.</i> (2012), Wetmore <i>et al.</i> (2013), and Wetmore (2015).
<code>httkpop_generate</code>	Generates a virtual population.
<code>lump_tissues</code>	Lumps tissue flows, volumes, and input partition coefficients based on specified grouping.

Table 4: List of functions in the package – Part I. Models are described in Table 2. Parameters are defined in Table 1. Jarnac and SBML are external languages for systems biology models.

Function	Description
<code>monte_carlo</code>	Runs a Monte Carlo simulation of a given model.
<code>parameterize_1comp</code>	Parameterizes the model 1compartment.
<code>parameterize_3comp</code>	Parameterizes the model 3compartment.
<code>parameterize_pbtk</code>	Parameterizes the model pbtk.
<code>parameterize_schmitt</code>	Parameterizes <code>predict_partitioning_schmitt</code> .
<code>parameterize_steadystate</code>	Parameterizes the model 3compartmentss, used in <a href="#">Wetmore et al. (2012)</a> and <a href="#">Wetmore (2015)</a> .
<code>predict_partitioning_schmitt</code>	Predicts partition coefficients using Schmitt's method ( <a href="#">Schmitt 2008b</a> ).
<code>solve_1comp</code>	Solves the model 1compartment.
<code>solve_3comp</code>	Solves the model 3compartment.
<code>solve_pbtk</code>	Solves the model pbtk.

Table 5: List of functions in the package – Part II. Models are described in Table 2. Parameters are defined in Table 1. Jarnac and SBML are external languages for systems biology models.

```
R> table <- NULL
R> for (this.cas in intersect(get_cheminfo(model = "pbtk"),
+   get_wetmore_cheminfo())) {
+   this.row <- as.data.frame(this.cas)
+   this.row <- cbind(this.row, as.data.frame(calc_analytic_css(
+     chem.cas = this.cas, model = "pbtk", output.units = "mg/L")))
+   this.row <- cbind(this.row, as.data.frame(get_wetmore_css(
+     chem.cas = this.cas, which.quantile = 0.50)))
+   this.row <- cbind(this.row, as.data.frame(calc_mc_css(
+     chem.cas = this.cas, which.quantile = 0.50)))
+   table <- rbind(table, this.row)
+ }
R> colnames(table) <- c("CAS", "PBTk", "Wetmore", "MC")
```

### 3.3. Plotting

#### *Concentration vs. time*

The function `solve_pbtk` has the option of returning plots for the compartment concentrations vs. time, but to see how  $C_{ss}$  resulting from discrete dosing deviates from the average steady state concentration, we can make a plot with **ggplot2** that includes a horizontal line through the  $y$  axis at the predicted  $C_{ss}$  for oral infusion dosing (Figure 2). We calculate the analytic  $C_{ss}$  and enter it into `geom_hline` as the  $y$  intercept and add all the other options to our 'ggplot' object.

```
R> library("ggplot2")
R> out <- solve_pbtk(chem.name = "Bisphenol A", days = 50, doses.per.day = 3)
R> plot.data <- as.data.frame(out)
```

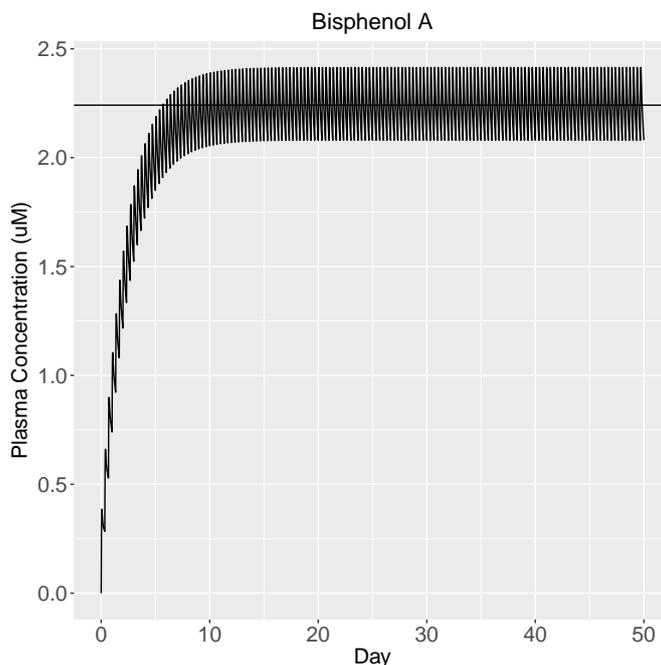

Figure 2:  $C_{ss}$  at 3 doses per day, 1 mg/kg BW/day.

```
R> css <- calc_analytic_css(chem.name = "Bisphenol A")
R> c.vs.t <- ggplot(plot.data, aes(time, Cplasma)) + geom_line() +
+   geom_hline(yintercept = css) + ylab("Plasma Concentration (uM)") +
+   xlab("Day") + theme(axis.text = element_text(size = 16),
+   axis.title = element_text(size = 16),
+   plot.title = element_text(size = 17, hjust = 0.5)) +
+   ggtitle("Bisphenol A")
R> c.vs.t
```

This example plots the concentration vs. time of 1 mg/kg BW/day of Bisphenol A broken into three doses per day. The same plots can be made for the other models by substituting one of the other two solve functions, `solve_3comp` or `solve_1comp`, for `solve_pbtk` and setting the `model` argument of `calc_analytic_css` to the corresponding model. These three functions also have the option of simulating a single oral or i.v. dose and setting the initial values of each compartment with units matching the specified output units (default is  $\mu\text{M}$ ).

### *Days to steady state histogram*

Creating histograms can allow us to visualize how a given value varies across all the chemicals contained within the package. To create a histogram using **ggplot2** of the number of days to steady state, we must first set up a for loop with `get_cheminfo` and `calc_css` to generate a vector containing the data. Vectors containing the average and maximum concentrations at steady state are also generated in this example, `avg` and `max`. The data contained in the `days` vector are then plotted as a histogram (Figure 3). We can just as easily create a histogram containing the average or maximum steady state concentrations by substituting `avg` or `max` for `days`.

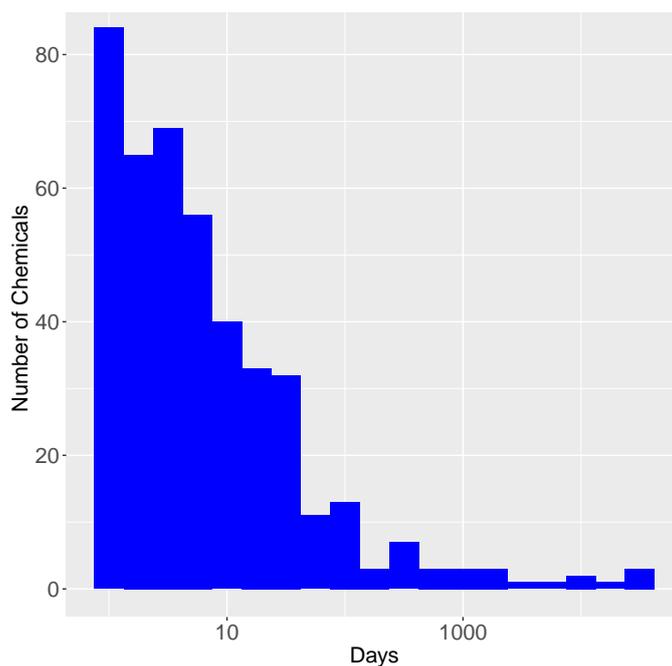

Figure 3: Days to steady state histogram.

```
R> library("ggplot2")
R> days <- NULL; avg <- NULL; max <- NULL
R> for (this.cas in get_cheminfo(model="pbtck")) {
+   css.info <- calc_css(chem.cas = this.cas, doses.per.day = 1,
+     suppress.messages = TRUE)
+   days[[this.cas]] <- css.info[["the.day"]]
+   avg[[this.cas]] <- css.info[["avg"]]
+   max[[this.cas]] <- css.info[["max"]]
+ }
R> days.data <- as.data.frame(days)
R> hist <- ggplot(days.data, aes(days)) +
+   geom_histogram(fill = "blue", binwidth = 1/4) + scale_x_log10() +
+   ylab("Number of Chemicals") + xlab("Days") + theme(axis.text =
+   element_text(size = 16), axis.title = element_text(size = 16))
R> hist
```

#### *Average vs. maximum concentration*

We can compare the average and maximum concentrations at steady state using the average and maximum concentration at steady state vectors, `avg` and `max`, from the previous example. The vectors are bound into a data frame and plotted with a line through the origin with a slope of 1 (Figure 4).

```
R> library("ggplot2")
R> avg.max.data <- data.frame(avg, max)
```

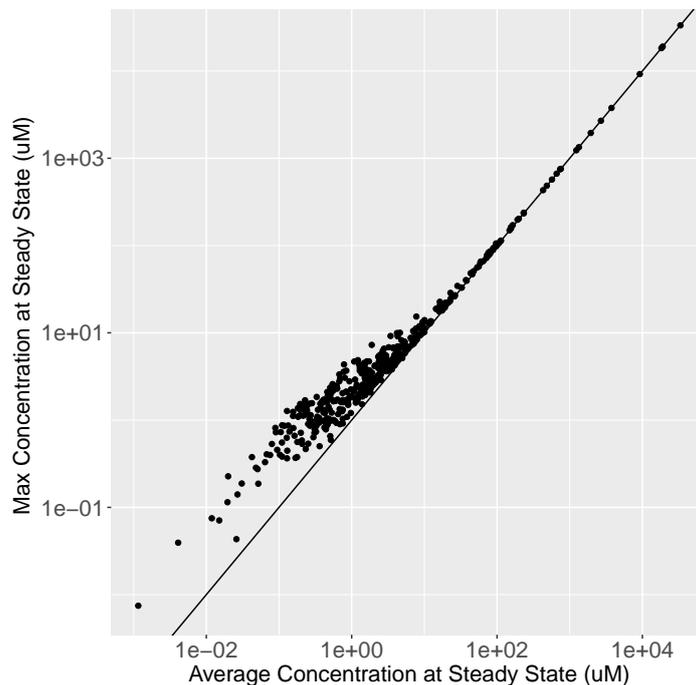

Figure 4: Average vs. maximum concentration at steady state for 1 dose per day, 1 mg/kg BW/day.

```
R> avg.vs.max <- ggplot(avg.max.data, aes(avg, max)) + geom_point() +
+   geom_abline() + scale_x_log10() + scale_y_log10() +
+   xlab("Average Concentration at Steady State (uM)") +
+   ylab("Max Concentration at Steady State (uM)") +
+   theme(axis.text = element_text(size = 16),
+   axis.title = element_text(size = 16))
R> avg.vs.max
```

### 3.4. Calculating AUC, peak, and mean values

The function `calc_stats` calculates the area under the curve (AUC), peak, and mean concentrations of any of the solve functions. If a chemical name or CAS number is specified, it will calculate the specified statistics for that chemical, and if not, it will calculate the values for all chemicals with sufficient data. To calculate the peak statistics for all chemicals simulated for 10 days at 1 mg/kg BW/day with 3 doses per day and a list containing the AUC, peak, and mean for a single 1 mg dose of triclosan over 10 days, we have:

```
R> all.peak.stats <- calc_stats(days = 10, doses.per.day = 3, stats = "peak")
R> triclosan.stats <- calc_stats(days = 10, chem.name = "triclosan")
```

### 3.5. Monte Carlo sampler

The functions `calc_mc_css` and `get_wetmore_css` generate  $C_{ss}$  vectors of Monte Carlo samples and their quantiles. While `calc_mc_css` generates new values using the sampler,

`get_wetmore_css` retrieves literature values from `Wetmore.data`. Below are examples of these two functions, comparing the medians of the Wetmore data in humans for 1 mg/kg BW/day of Bisphenol A with the `calc_mc_css` simulation with probability distributions containing a third of the standard deviation, half the limit of detection for  $f_{ub}$ , and double the number of samples of the parameters used in [Wetmore \*et al.\* \(2012\)](#) and [Wetmore \(2015\)](#). These examples do not make use of H<sub>1</sub>TK-Pop, but vignettes describing the use of H<sub>1</sub>TK-Pop Monte Carlo sampler for human variability ([Ring \*et al.\* 2017](#)) are included in the package.

```
R> get_wetmore_css(chem.cas = "80-05-7", daily.dose = 1,
+   which.quantile = 0.5, output.units = "uM")
R> calc_mc_css(chem.cas = "80-05-7", daily.dose = 1, which.quantile = 0.5,
+   censored.params = list(Funbound.plasma = list(cv = 0.1, lod = 0.005)),
+   vary.params = list(BW = 0.15, Vliverc = 0.15, Qgfr = 0.15,
+   Qtotal.liverc = 0.15, million.cells.per.gliver = 0.15, Clint = 0.15),
+   output.units = "uM", samples = 2000, httkpop = FALSE)
```

The oral equivalent functions convert  $C_{ss}$  into a dose. Below is an example of a 50  $\mu$ M  $C_{ss}$  of Bisphenol A converted to an oral equivalent dose using the Wetmore data for the 95th quantile of human  $C_{ss}$ . We can call `calc_mc_oral_equiv` in the same manner, passing additional arguments to `calc_mc_css` within the function and specifying any quantile we want.

```
R> get_wetmore_oral_equiv(50, chem.cas = "80-05-7")
```

We can also use the original Monte Carlo sampler used in `calc_mc_css`, `monte_carlo`, to perform the same simulations using another model. Setting the `return.samples` argument of the `calc_mc` or `monte_carlo` functions to `TRUE`, we can generate the sampling distribution for the Monte Carlo simulation from which the quantiles are calculated. To perform a Monte Carlo simulation on zoxamide (Figure 5) with the model `pbtck` with the same limit of detection and coefficients of variation of two thirds the size of those used in `calc_mc_css`, we have:

```
R> vary.params <- NULL
R> params <- parameterize_pbtck(chem.name = "Zoxamide")
R> for (this.param in names(subset(params,
+   names(params) != "Funbound.plasma")))) vary.params[this.param] <- 0.2
R> censored.params <- list(Funbound.plasma = list(cv = 0.2, lod = 0.01))
R> set.seed(1)
R> out <- monte_carlo(params, cv.params = vary.params,
+   censored.params = censored.params, return.samples = TRUE,
+   model = "pbtck", suppress.messages = TRUE)
R> zoxamide <- ggplot(as.data.frame(out), aes(out)) +
+   geom_histogram(fill = "blue", binwidth = 1/6) + scale_x_log10() +
+   ylab("Number of Samples") + xlab("Steady State Concentration (uM)") +
+   theme(axis.text = element_text(size = 16),
+   axis.title = element_text(size = 16))
R> zoxamide
```

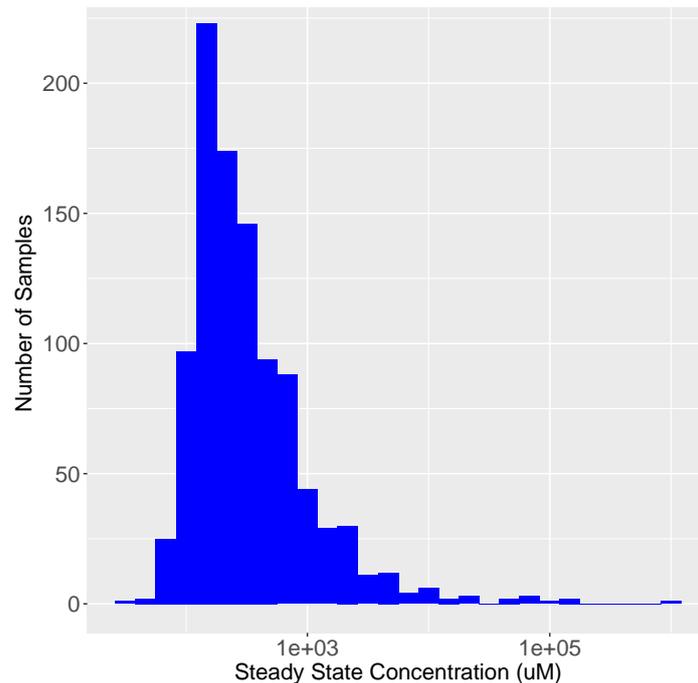

Figure 5: Sampling distribution of zoxomide  $C_{ss}$  from the model `pbtk`.

The `out` vector is then plotted in a similar way to the `days` vector in the previous histogram example. This can also be performed with the new sampler in `calc_mc_css` by simply setting `model` to `"pbtk"`.

### 3.6. Adding a tissue

The fractional volumes and pH values from [Schmitt \(2008a\)](#) needed to calculate the partition coefficients are contained in `tissue.data`. New tissues can be added to this table to generate their partition coefficients. We can add thyroid to the tissue data by making a row containing its data, subtracting the volumes and flows from the rest-of-body, and binding the row to `tissue.data`. Here we assume it contains the same partition coefficient data as the spleen and a tenth of the volume and blood flow:

```
R> new.tissue <- subset(tissue.data, Tissue == "spleen")
R> new.tissue[, "Tissue"] <- "thyroid"
R> new.tissue[new.tissue$variable %in% c("Vol (L/kg)",
+   "Flow (mL/min/kg^(3/4))"), "value"] <- new.tissue[new.tissue$variable
+   %in% c("Vol (L/kg)", "Flow (mL/min/kg^(3/4))"), "value"] / 10
R> tissue.data[tissue.data$Tissue == "rest", "value"] <-
+   tissue.data[tissue.data$Tissue == "rest", "value"] -
+   new.tissue[new.tissue$variable %in% c("Vol (L/kg)",
+   "Flow (mL/min/kg^(3/4))"), "value"]
R> tissue.data <- rbind(tissue.data, new.tissue)
```

We can also choose what tissues we want lumped together or in the rest-of-body compartment. The `tissuelist` argument in `parameterize_pbtk` contains a list of the desired compartment

names, each containing a vector of the names of the tissues in `tissue.data` to be lumped together in that compartment. All unspecified tissues in `tissue.data` are lumped together in the rest-of-body. Lumped flows and volumes are calculated through addition of the individual component flows and volumes while the lumped partition coefficients are calculated through dividing the sum of the products of the partition coefficients and their corresponding compartment volumes by the new lumped volume. To generate the parameters for a model with kidneys, thyroid, a liver compartment combining the liver and gut, and a rest-of-body compartment:

```
R> compartments <- list(liver = c("liver", "gut"), kidney = "kidney",  
+   thyroid = "thyroid")  
R> parameterize_pbtk(chem.name = "Nicotine", tissuelist = compartments)
```

No matter which compartments we specify, the liver volume as well as the gut, liver, and kidney flows are returned for the calculation of clearance and metabolism.

### 3.7. Export functions

Jarnac (Sauro and Fell 2000) and SBML (Hucka *et al.* 2003) are commonly used languages for systems biology models of cellular and physiological processes. In the event that a modeler wishes to couple such a model to a toxicokinetic model, we provide functions to export model equations and chemical-specific parameters to these languages. The two functions, `export_pbtk_sbml` and `export_pbtk_jarnac`, have the same arguments and only differ in the file extension names (.xml and .jan) entered into the `filename` argument. Both use liters as the units for volume, but the amounts are unitless and to be determined by the user. If we suppose that we enter an initial amount of 1 mg in the gut lumen, then all the other compartments will contain amounts in mg. Below is a call of an export function for a dose of 1 given to a rat.

```
R> export_pbtk_sbml(chem.name = "Bisphenol A", species = "Rat",  
+   initial.amounts = list(Agutlumen = 1), filename = "PBTKmodel.xml")
```

## 4. Concluding remarks

The R software platform is increasingly being used for the statistical analysis of mathematical models (Wambaugh *et al.* 2015; Gelman *et al.* 2013). With the launch of the package `odesolve` (Setzer 2001), which was expanded and replaced by `deSolve` (Soetaert *et al.* 2010), R can be used to solve models consisting of systems of differential equations. R further allows organization and handling of large data sets, making it especially suitable for analyzing the results from high-throughput experiments (Judson *et al.* 2010). Given the reliance on mathematical models and *in vitro* testing to prioritize investigation of the large number of relatively untested environmental chemicals (Wetmore *et al.* 2012; Wetmore 2015), software platforms such as R allow the systematic statistical evaluation of the performance of these technologies (Wambaugh *et al.* 2015). `httk` allows the simulation of four toxicokinetic models for 553 chemicals (including 415 ToxCast chemicals and 94 pharmaceuticals) in humans, rats, mice, dogs, and rabbits.

All models in **httk** are parameterized using data on key determinants of toxicokinetics that can be measured *in vitro* using relatively high-throughput methods (Wetmore *et al.* 2012; Wetmore 2015). The package includes toxicokinetic models ranging from a one compartment model to a PBTK model, but even the PBTK model is relatively sparse, with most tissues lumped into a rest-of-body compartment. Rowland (2004) argued that the “best” model is the one that most reliably answers the question at hand (Rowland *et al.* 2004). Thus, the most parsimonious model – that is, the simplest, most easily understood model allowing useful predictions – should be preferred (Chiu and White 2006). However, since PBTK models allow the incorporation of additional, physiological information, we may expect our model `pbtk` to be the most accurate on average. We hope these models provide predictions of chemical-specific toxicokinetics as informed by *in vitro* data and physicochemical properties without introducing errors from unnecessary assumptions (Rowland *et al.* 2004; Chiu and White 2006). The `parameterize_pbtk` function provides parameter estimates for more complex models as needed (Yang and Lu 2007), though our solvers are currently limited to the four model structures. In future versions, we expect to have the ability to add new compartments using these parameters and simulate dermal and inhalation exposure.

The **httk** package provides functions for the application of Monte Carlo methods, *in vitro-in vivo* extrapolation, and reverse dosimetry. **httk** links exposure scenarios, including constant oral infusion, a single dose, or multiple discrete doses, to predicted tissue and plasma concentrations. Standard toxicokinetic statistics including peak concentration and time-integrated plasma concentration (area under the curve or AUC) can be predicted, facilitating dosimetric anchoring (Wambaugh *et al.* 2013a) for comparing *in vivo* toxicity studies where toxicokinetic data were not collected (Wetmore *et al.* 2013). Important aspects of the steady-state behavior of the chemicals can be predicted for use in analysis of biomonitoring data, including the time to steady-state and  $C_{ss}$  (Wetmore *et al.* 2012; Wetmore 2015; Aylward and Hays 2011; Wambaugh *et al.* 2013b, 2014). Finally, as ongoing *in vitro* experiments allow parameterization of the models for additional chemicals, these new data can be easily distributed as updates to the package on the CRAN repository.

## Acknowledgments

The authors appreciate editorial comments from Nicole Kleinstreuer and Kevin M. Crofton, help with the Schmitt algorithm from Jimena Davis, help with `Jarnac` from James Sluka, and chemical properties and *in vivo* data provided by the Netherlands Organization for Applied Scientific Research (TNO) through Sieto Bosgra.
