Make time for time series statistics

Many data include time or have longitudinal dimensions. When these data include an index of time, i.e., measures at regular or periodically successive intervals, statistics that use time sequencing in some capacity are appropriate (Senin 2009). There are at least two major categories of statistics – ‘time series analysis’ to examine trends and address potential periodicity in the data and ‘time series forecasting’ that incorporates time into models with the intent of predicting future outcomes (Senin 2009). Most major disciplines of data exploration now use either or both of these categories of statistics to examine patterns or infer causality (De Gooijer and Hyndman 2006). Consequently, investing time into a comprehensive text on these topics is not lost time.

Content

This is a second edition. Two major suggestions associated with the former edition – incorporate R and provide more real-world empirical examples are addressed. This edition excels in both these respects. At the end of most chapters and in many instances interspersed within sections, R commands and links to the package `tswge` are clearly referenced. There are a total of 249 time series packages currently available in the CRAN task view “Time Series Analysis” (Hyndman 2018), and it is a strength to have a package formally link to a detailed text as is the case here. This provides a compelling case for statistics with the `tswge` package and the text for comprehension of the maths and application. The reader should be prepared for formulas, proofs, and a description of the functions within the R package `tswge` and should be relatively fluent in all three domains. Structurally, the appendices are provided at the end of each section within every chapter. This is ideal because the implementation of the theory is thus readily at hand. Examples are also included *in situ* and threaded throughout the book for various topics. Notes, theorems, proofs, and annotations are also included.

This is first and foremost a statistics book (Woodward, Gray, and Elliott 2017). It is an extraordinarily thorough statistics text, but the reader must be relatively expert. The general context of time series is underdeveloped typically lacking a sufficient general, natural language preamble to most topics. It is assumed that a. the reader is already familiar with time series to some extent and b. the reader is competent and able to parse the maths and proofs associated with relevant axioms to particular aspects of time series. This is unfortunate because the general utility of and decision to implement time series are important and evolving (Mishra, Soni, Sharma, and Upadhyay 2017), non-trivial (Webby and O'Connor 1996), and at times complex (Fu 2011; Tang, Lv, Yang, and Yu 2015). The purpose, class, and different forms of data that can comprise time series all shape subsequent analyses, and without a guide for the reader in making these decisions, it is challenging to know what specific chapters are relevant to the task at hand. Admittedly, this is very pragmatic perspective for a statistical text, but unification and integration at the start of the book would be helpful to the reader. This is done to some extent by the examples provided, but the description resolves very rapidly into details.

Critique

The authors have extensive experience with time series. Too rarely within the text is this expertise invoked to directly guide the reader. Two notable exceptions include the chapter on model identification and the chapter on model building. In each instance, the authors relax the prose to an extent and state personal preferences in selecting models and how to best do this. In the latter instance, the authors further provide a summary that describes an expert workflow in working with models for time series. This is invaluable. The choice to commit time to a statistical text versus long-form documentation such as vignettes within the R ecosystem should provide the reader with rewards in depth and in expertise and description of reasoning that is typically not provided in relatively shorter treatments of topics. The depth is provided in this text but more of the larger, expert insights could also have been offered. The linkages to theory are sufficient, but other alternatives in R were not developed. There are also over 100 similar texts listed on Amazon and many free ebook alternatives. Consequently, a statement by the authors not just on the differences to a former edition, but on the specific niche that this book fulfills would have been helpful. The commitment to digest this particular book is substantive, and each major class of analysis and forecasting is provided. The strongest and likely most unique contributions to the field are provided in Chapters 7–10 wherein parameter estimation, models, and multivariate time series are described. These sections warrant the commitment, but a more landscape-level view of time series is best secured in other resources. In summary, this is an excellent advanced text that does not shy away from maths to describe time series and delivers a detailed appreciation and workflow to parameters and models. However, additional reading will be needed to be able to comprehend general theory for time series. The R package `tswge` that is anchored to this text is impressive, and can be applied to most aspects of time series analyses. Ideal use for this text would be those with experience in time series but that seek to further develop and ground their knowledge in theory and maths that underpin the statistics.
